Division finds an unknown factor

I can… use multiplication to solve an unknown-factor problem.

What factor is missing?

$6 \times ? = 42$

Think multiplication to divide

$42 \div 6 = ? \rightarrow 6 \times 7 = 42$

The missing factor is 7.

Check the relationship

$42 \div 7 = 6$

Multiplication and division describe the same equal groups from different starting points.
